Family PELECINIDAE

Taxonomy: Schulz, 1903. Bayer. Akad. der Wiss., Math.-Phys. Kl. Sitzber., p. 435.

Genus **PELECINUS** Latreille

Pelecinus Latreille, 1800. Bul. Sci. Soc. Philom. Paris 2 (44): 155.

Type: (*Ichneumon polycerator* Fabricius) = *Ichneumon polyturator* Drury. Monob.

Epiceuastes Gistel, 1848. Naturgesch. Thierr. f. höh. Schul., p. X, col. 1. Unnecessarily proposed for *Pelecinus* Latreille.

Biology: Clausen, 1940. Entomophagous Insects, pp. 270-271.—Hammond, 1944. Canad. Ent. 74: 130.

Taxonomy: Brues, 1928. Psyche 35: 205-209.

This genus, which comprises the family Pelecinidae, is a peculiar genus, conspicuously distinct from all other families of the Proctotrupoidea although apparently belonging in this group, and with the two sexes strikingly dimorphic. It appears to be represented in North America by a single extremely variable species, but no really critical study of the large accumulations of specimens that are to be found in the principal insect collections has ever been attempted. Such a study, supplemented by more information on biology, may prove this segregate to be a complex of several distinct species. The present meager records pertaining to biology and host relations indicate that *Pelecinus* parasitizes the larvae of soil-inhabiting Scarabaeidae.

Superfamily **CHRYSIDOIDEA**²⁴

Family **CHRYSIDIDAE**

The North American forms of these brilliantly metallic blue and green wasps, popularly known as gold- or cuckoo-wasps, occur asinquilines or parasites in the nests of solitary bees and wasps. The group is of little economic importance although an unsuccessful attempt was made to establish a Chinese parasite (*Chrysis shanghaiensis* Smith) of the oriental moth in Massachusetts.

Taxonomic work in this family is complicated by lack of information on the biology of the group since a knowledge of host relationships is essential for the proper understanding of the various species complexes. It is anticipated that many changes will be made in the synonymy as biological data become available.

Superfamily BETHYLOIDEA²⁵

Family BETHYLIDAE

This family, and even its North American representation, is by no means as small as is suggested by the following record of described species.

²⁵By C. F. W. Muesebeck and Luella M. Walkley, U. S. Bureau of Entomology and Plant Quarantine.

The Nearctic Bethyridae have never been intensely collected or critically studied, and comparatively little is known about their biology. The group should prove a very attractive one to an energetic and competent student of Hymenoptera. Apparently its closest affinities are with the Cleptidae in the Chrysidoidea.

Family TRIGONALIDAE²⁶

The trigonalids are parasites, either of social Vespidae or of the parasites of caterpillars. Their minute and very numerous eggs are laid at random on foliage and subsequently eaten by caterpillars. In the case of secondary parasites of caterpillars the eggs hatch in the gut of the caterpillar and the trigonalid larva enters the body of the caterpillar to attack an ichneumonid, tachinid, or other parasitic larva. Trigonalids parasitic on the larvae of social vespids are presumably brought to the vespid larvae with their caterpillar food.

²⁷ This section was prepared by Karl V. Krombein, U. S. Bureau of Entomology and Plant Quarantine, except for the part comprising the family Sapygidae, which was prepared by Richard M. Bohart, University of California, Davis, Calif.

So far as is known species of this genus parasitize larvae of various Scarabaeidae (Coleoptera). Detailed liberation records of the Oriental species released in the United States for control of the introduced *Popillia*, *Anomala*, *Autoserica*, and *Serica* were published by Krombein (1948, Ent. Soc. Amer. Ann. 41: 58-62). Of the liberated species only *vernalis* Rohwer, *popilliavora* Rohwer, and *asericae* Allen and Jaynes established themselves; *sternata* Parker is doubtfully established; *bicarinata* Cameron, *biseculata* Allen and Jaynes, *castaneaeavora* Parker, *frater* Parker, *matura* Allen and Jaynes, *notopolita* var. *alleni* Roberts, *pullivora* Allen and Jaynes, and *totopunctata* Allen and Jaynes apparently did not become established.

Family SIEROLOMORPHIDAE

Taxonomy: Melander and Brues, 1932. Harvard Univ., Mus. Compar. Zool. Bul. 73: 500.—Schuster, 1949. Ent. Amer. (n. s.) 29: 124-125.

Genus SIEROLOMORPHA Ashmead

Sierolomorpha Ashmead, 1903. Canad. Ent. 35: 42.

Type: *Sierola* (?) *ambigua* Ashmead. Monob.

Taxonomy: Rohwer, 1911. U. S. Natl. Mus. Proc. 40: 551.

The genus is rather widely distributed in North America (specimens have been seen from New York, Maryland, Georgia, Florida, Louisiana, Texas, New Mexico, Ohio, Illinois, Iowa, North Dakota and Idaho), and

represented by several distinct species. It is impossible here to elucidate the component forms. The Hawaiian *hospes* Perkins may have been introduced from North America.

Family MUTILLIDAE

The author is indebted to Prof. C. E. Mickel and Dr. R. M. Schuster for reading over the first draft of this section. Prof. Mickel has suggested some of the new synonymy proposed herein, and he has been recorded as the authority for it after each pertinent citation.

So far as is known, the North American species of this family, some of which are popularly called "velvet ants" or "cow killers," are parasitic on other aculeate Hymenoptera, mostly on ground-nesting forms.

Subfamily APTEROGYNINAE

Tribe CHYPHOTINI

Genus CHYPHOTES Blake

Chyphotes Blake, 1886. Amer. Ent. Soc. Trans. 13: 276.

Type: *Chyphotes elevatus* Blake. Monob. and orig. desig.

Blaketa Pate, 1948. Ent. News 59: 41. N. name.

Revision: Buzicky, 1941. Ent. Amer. 21 (n. s.): 201-243.

Pate states that *Chyphotes* Blake is a homonym of *Cyphotes* Burmeister, 1835, since both have the same etymology (Opin. 147, Internatl. Comn. Zool. Nomencl.). Inasmuch as *Chyphotes* is the basis for a tribal name in the Mutillidae and has been used in the modern revision of the group, it would be desirable to conserve it if possible. Since Blake gives no derivation for his name, it is recommended that the name be considered an arbitrary combination of letters (Article 8, Recommendation k, Internatl. Rules Zool. Nomencl.), and therefore not of the same derivation as *Cyphotes*. *Chyphotes* and *Cyphotes* are widely separated zoologically as well as alphabetically, so no confusion should arise from having both names in current usage.

Family FORMICIDAE²⁹

Ants are social insects that live in colonies in diverse situations, more commonly in the ground or in rotting wood. Some are general feeders; others have highly specialized food habits. Although most ants are free-living forms, some are parasites on other species of ants or live asinquilines with them. A number of forms are of concern to man because of their feeding, nesting or stinging habits. A colony is normally composed of one of more reproductive females and workers, and at certain seasons of the year it contains also males and virgin females.

Subfamily DORYLINAE

The legionary ants are the New World equivalent of the Old World driver or army ants. Highly predaceous, they are known for their foraging expeditions on other arthropods, including ants. They exhibit a number of peculiar developments not common to most ants, such as wasplike males, wingless, termitelike females, and often blind workers. The biology of most of the forms is not well known.

Revision: Emery, 1895. Zool. Jahrb. Abt. f. System. 8: 264-266.

Although most common in southeastern United States, ants of this genus have been found as far north as New York and as far west as Kansas and Texas. They usually nest in well-rotted, moist wood such as that of stumps and logs; and the colonies are small, seldom containing more than two or three dozen individuals. The workers are sluggish, hypogaecic, and entomophagous.

Subfamily MYRMICINAE

This is the largest subfamily and the most diverse with respect to size, shape, structure, and habits. Moreover, it contains more forms inimical to man than any other group of ants. Nests are constructed in soil, wood, crevices of plants, debris, insect galls, buildings, ships, and in many other situations. The feeding habits are highly varied; and some forms have restricted diets, whereas others are general feeders.

Note.—*Myrmica rubra neolaevinodis* Forel, 1901, Naturhist. Mus. Hamburg Mitt., ♀, was described by Forel along with the statement, "from New York with iris roots." As Forel had no definite proof that the iris from which the ants were collected had come from New York, this form is not listed along with the other Nearctic *Myrmica*.

Subgenus MANICA Jurine

Manica Jurine, 1807. Nouv. Méth. Class. Hym. Dipt., p. 276.

Type: *Formica rubida* Latreille. Desig. by W. M. Wheeler, 1911.

Aphaenogaster subg. *Neomyrma* Forel, 1914. Rev. Suisse Zool. 22: 275.

Type: (*Aphaenogaster* (*Neomyrma*) *calderoni* Forel) = *Myrmica bradleyi* W. M. Wheeler. Monob.

Myrmica subg. *Oreomyrma* W. M. Wheeler, 1914. Psyche 21: 118.

Type: *Formica rubida* Latreille. Orig. desig.

Revision: W. M. Wheeler, 1914. Psyche 21: 118-122.

Apparently restricted to western Canada and United States, no specimens having been recorded farther east than the Badlands of North Dakota (approximately 103rd to 104th degree of longitude). These ants commonly nest in creek or river bottoms in the soil or beneath stones where the soil is sandy, gravelly or silty. The colonies are often small.

These ants nest in moderately large colonies in the soil, wood, crevices of plants, insect galls, carton nests of their own making, and even in buildings. Some are well known house-infesting forms; others have been reported to kill young birds and even to gnaw the rubber insulation from telephone wires. Two apparently workerless species have been found to live as parasites in the nests of closely related forms of *Crematogaster*.

Heat-loving forms which usually nest in the soil but sometimes in the rotten wood and occasionally in houses. The colonies are usually populous, and the workers are aggressive. They are carnivorous, granivorous, predaceous, and also feed on honeydew. Most of the Nearctic forms are serious pests, stealing seeds from seed beds, killing young quail and poultry or even small game, gnawing into vegetables, fruits, flowers, crops and fabrics, attending or fostering honeydew-excreting insects, damaging telephone equipment, making ugly mounds on lawns, and girdling young nursery trees. The workers of one form have been shown to carry viable dysentery germs for at least 24 hours on their bodies.

Revision: Emery, 1895. Zool. Jahrb. Abt. f. System. 8: 272-274.

This genus is represented by a single form, *pergandei*, which was collected from a colony of *Monomorium minimum* (Buckl.). The host colony contained only winged males and winged females. As only males and females of *Epoecus* were noted, the ants of this genus are supposed to be workerless and parasitic.

Palaearctic. Presumably introduced into the United States with the host ant. A permanent parasite on colonies of *Tetramorium caespitum* (L.). Parasitized colonies of that ant are rare, and contain only workers of the host species. Workers are entirely lacking in *Anergates*. The virgin females of *Anergates* are winged, the males, wingless, pupoid. As the parasites are entirely dependent on the host for food and care, a colony dies out when all the host workers die.

Leptothorax Mayr, 1855. Zool.-Bot. Gesell. Wien, Verh. 5: 431.

Type: *Formica acervorum* Fabricius. Desig. by Bingham, 1903.

Mychothorax Ruzsky, 1904. Sapiski Imp. Russ. Geog. Obschtsch. 41: 288.

Type: *Formica acervorum* Fabricius. Orig. desig.

Holarctic. In the United States confined largely to the northern and western states. The ants live in living and dead trees, logs, stumps, decaying wood, soil, insect galls, and nests of other ants. Colonies are small to moderate in size. Many forms are free living but some areinquilines in the nests of other ants.

acervorum canadensis Provancher. Labrador, Canada, north. U. S. and Alaska; Colo. *L. acervorum acervorum* (Fabricius) occurs in Europe, Russia, Central Asia. Boreal in distribution. Enslaved by *Harpagozenus canadensis* M. R. Smith. This ant has been found at latitude 69° 22' N., the northernmost record of any New World ant.

Peculiar to the Old World, especially the Ethiopian Region. The group contains many important economic forms. All of those occurring in the Nearctic Region are thought to have been introduced.

- caespitum** (Linnaeus). Europe, Asia, U. S. Most abundant in the states along the Atlantic Seaboard, becoming more sporadically distributed farther inland. An important economic species; infests houses, steals seed from seed beds, gnaws into tubers, roots, and stalks of flowers and vegetables, attends honeydew-excreting insects. The colonies are populous. Host of parasitic ants belonging to the genera *Anergates* and *Strongylognathus*.

Almost cosmopolitan. The Nearctic forms nest in small colonies in the soil, or humus, usually beneath objects; also in decayed wood,

cavities of plants, and nuts on the ground. Nests are often located near or within colonies of other ants. It has been assumed that members of this group are thief ants. The Wesson brothers have definitely found some of the forms predaceous on collembolans.

Type: *Atta (Mycetosoritis) hartmanni* W. M. Wheeler. Monob.

Neotropical and Nearctic (southern United States). Intermediate
in form between *Cyphomyrmex* and *Trachymyrmex* but with habits more
like those of the latter genus. Very small colonies are formed in the
soil. The food consists of a fungus grown upon a substratum composed
of the anthers of plants. The workers are thought to be nocturnal or
crepuscular.

Neotropical and Nearctic, occurring as far north as Long Island,
N. Y. Although most forms are recorded from the more humid areas of
the United States, a few occur even in arid sections. The fungi on which
the ants feed is grown on a substratum of plant particles and insect
excrement.

Neotropical with a slight extension into the Nearctic Region (Ariz., Calif., Tex.). Our common form, *versicolor versicolor* (Perg.), is apparently largely confined to arroyos in arid areas where the ants nest in the soil. The habits are very similar to those of *Atta texana* Buckl. but colonies are apparently not so large and the leaf-cutting habits are not on so extensive a scale.

Neotropical with an extension into the Nearctic Region (Ariz., La., Tex.). Two forms occur in the United States, *A. mexicana* in southern Arizona and *A. texana* in Louisiana and Texas. Nests, which are deep in the soil and usually have many lateral and vertical entrances, are often extremely large and contain innumerable individuals. Workers defoliate both wild and domesticated plants, including trees. The ants live on a fungus grown from a substratum composed of macerated leaves and other vegetable matter.

More common in southern United States than elsewhere.

Genus DOLICHODERUS Lund

Subgenus DOLICHODERUS Lund

Dolichoderus Lund, 1831. Ann. des Sci. Nat., Zool. 23: 130.

Type: *Formica attelaboides* Fabricius. Monob.

Not known to occur in the Nearctic Region.

Subgenus HYPOCLINEA Mayr

Hypoclinea Mayr, 1855. Zool.-Bot. Gesell. Wien, Verh. 5: 377.

Type: *Formica quadripunctata* Linnaeus. Desig. by W. M. Wheeler, 1911.

Revisions: Mayr, 1870. Zool.-Bot. Gesell. Wien, Verh. 20: 953-960.—Mayr, 1886. Zool.-Bot. Gesell. Wien, Verh. 36: 434-437.—W. M. Wheeler, 1905. Amer. Mus. Nat. Hist. Bul. 21: 305-319.

In the United States the genus ranges from Canada to the Gulf of Mexico and as far west as approximately the 104th degree of longitude. Colonies are small to moderately large. Nests are constructed in the soil, in curled leaves and hollow stems of plants, and in cartons attached to plants. Workers attend honeydew-excreting insects and feed on small arthropods. Some forms emit a fluid from their anal glands which has a peculiar smoky or pungent odor. So far as is known, none of the species is of any economic importance.

humilis (Mayr). Md. to Fla., west to Ill. and Calif. Introduced into the United States from Brazil; becoming widely distributed over the world by commerce. This is the notorious "Argentine ant." It usually nests in the soil, rotting wood or debris, and lives in large colonies that contain many females. It destroys all the native species in its territory except a few insignificant ones, and is one of the worst of the known house-infesting ants. It is known to steal seeds from seedbeds, drive poultry from their nests, kill newly hatched chickens, foster honeydew-excreting insects, disrupt bee hives, and gnaw into ripened fruits.

Formica (*Hypochira*) subspinosa Buckley, 1866. Ent. Soc. Phila. Proc. 6: 169 ♀.

Subfamily FORMICINAE

Second largest subfamily of ants. Although representatives occur in every section, these ants are relatively more abundant in northern areas than elsewhere. Nests are constructed in diverse places, as in the soil, in logs and stumps, in crevices of plants and trees, in insect galls or even in houses. The food includes honeydew, sap, juices of plants and fruits, flesh of arthropods, etc. Some forms even foster mealybugs, plant lice, and possibly other honeydew-excreting insects. Many of them infest houses. One of the most troublesome is the black carpenter ant, *Camponotus herculeanus pennsylvanicus*, which not only infests human foods but may nest in the woodwork and cause appreciable injury. This ant is also known to damage telephone poles.

The Nearctic forms nest in insect galls, in branches and stems of plants, under bark of trees, in wood and buildings, and even in the soil. Colonies are small, consisting of a few dozen to several hundred individuals. The food is largely honeydew and the flesh of arthropods. A number of forms infest human foods, especially sweets, and some of them apparently nest in houses. The group is badly in need of revision.

Subgenus PARATRECHINA Motschoulsky

Paratrechina Motschoulsky, 1863. Soc. Nat. Moscou Bul. 36: 13.

Type: (*Paratrechina currens* Motschoulsky)=*Formica longicornis* Latreille. Desig. by W. M. Wheeler, 1911.

The single known species, thought to be a native of India, has been distributed by commerce over the world. In the United States this ant is now well established in towns and cities of the Gulf and Atlantic States; farther inland its distribution is sporadic. In the more northern areas the species lives in greenhouses or apartment buildings.

In the northern sections ants of this subgenus occur in greenhouses; farther south they are capable of living outdoors. The native species nest in soil and rotting wood. Some forms infest human foods, showing an especial fondness for sweets. Although easily recognized generically the ants are difficult to determine specifically. Male genitalia are believed to offer the best characters for separating the species.

Genus PRENOLEPIS Mayr

Prenolepis Mayr, 1861. Die Europäischen Formiceiden, pp. 26, 52.

Type: *Tapinoma nitens* Mayr. Desig. by Bingham, 1903.

Revisions: Emery, 1893. Zool. Jahrb., Abt. f. System. 7: 635-637.—W. M. Wheeler, 1930. Ent. Soc. Amer. Ann. 23: 1-26.

These ants usually nest in the soil openly or under cover in small to moderate-sized colonies. Workers feed on honeydew, secretions of floral and extrafloral nectaries, exudates from galls, earthworms and arthropods, and ripened or decaying fruits. The ants often invade houses in search of food, and they sometimes forage even at freezing temperatures. Repletes are common. Ants of this genus are among the first to take their nuptial flights in the spring, males and females having overwintered in their nests.

Distributed from Canada to Mexico. The ants nest in the soil, usually beneath objects, and also in rotting logs and stumps, and are

subterranean in habit. The females and workers have a characteristic citronella or lemon-verbena odor which no other forms of *Lasius* possess. Species of *Acanthomyops* are of some economic importance because they foster honeydew-excreting insects and because of their objectionable habit of nesting around foundations of buildings and beneath basement floors. The winged forms are often mistaken for termites.

Native to Mexico and western United States; especially typical of the arid plains and deserts of the Western States. The ants nest in the soil, usually in small colonies of only a few hundred individuals. Some forms are apparently entirely predaceous or carnivorous; others live on honeydew and nectar obtained from plants or the secretions of galls. Some are diurnal, others nocturnal. Repletes are known to occur in many forms. These ants are called "honey ants" because of the honeylike substance stored in the gasters of the repletes. Owing to the high degree of polymorphism in many forms, these ants are not easily determined specifically without large series of workers, especially major ones.

Genus FORMICA Linnaeus

One of the largest genera of ants. The genus includes the three subgenera *Proformica*, *Neoformica*, and *Formica*. For the sake of convenience the subgenus *Formica* has been split into five groups, called the fusca, rufa, microgyna, exsecta, and sanguinea groups. Ants of the genus *Formica* nest in both soil and rotting wood; they have an unusually wide distribution and occur in many diverse habitats. Their food is largely honeydew and small arthropods. Most forms are free living but some are temporary parasites; others are slave makers and still others are slaves.

Subgenus PROFORMICA Ruzsky

Proformica Ruzsky, 1903. Soc. Ent. Rossica Horae 36: 303.

Type: **Formica nasuta** Nylander. Desig. by W. M. Wheeler, 1911.

Revision: W. M. Wheeler, 1913. Harvard Univ., Mus. Compar. Zool. Bul. 53: 387, 399-400, 401-425.

These ants are distributed from Alaska to at least as far south as the 35th degree of latitude in the United States. The subgenus contains some of our smallest forms of *Formica*. The small colonies are usually constructed in the soil freely or under cover. The ants are timid and are enslaved by *Formica* of the sanguinea group.

Distribution solely Nearctic. In the United States, ants of the pallide-fulva group have been recorded from New Mexico and Wyoming eastward to the Atlantic Ocean and those of the moki group from Arizona, Utah, and Washington. These ants form colonies of small or moderate size in the soil openly or under cover. Some forms nest in rotting wood. Their food is largely honeydew and the flesh of small arthropods. They are docile and are enslaved by ants of the genus *Polyergus* and by various forms of *Formica sanguinea* Latr.

Revisions: Emery, 1893. Zool. Jahrb., Abt. f. System. 7: 643-654, 657-665, 663.—W. M. Wheeler, 1913. Harvard Univ., Mus. Compar. Zool. Bul. 53: 387-399, 401-536, 560-565.—Creighton, 1940. Amer. Mus. Novitates 1055: 1-10 (*rufa* subspecies).

This subgenus is divided into 5 groups, namely, the *fusca*, *sanguinea*, *exsecta*, *rufa*, and *microgyna* groups. Members of the *fusca* group are timid or docile and some are enslaved by certain forms of *Formica* (*F.*) *sanguinea* and *Polyergus*; others are hosts of temporary parasites of the *rufa*, *microgyna*, and *exsecta* groups. Most of the forms of *sanguinea* enslave other ants belonging to the *fusca* group and to the subgenera *Proformica* and *Neoformica*. The best known form of the *exsectoides* group is the Allegheny mound ant, *Formica exsectoides exsectoides*, whose large mounds attract the attention of the most casual observer. The *rufa* group contains forms that make conspicuous nests in rotting wood or in soil, which they cover with vegetable detritus. Many are temporary parasites on members of *Neoformica* and of the *fusca* group of *Formica*. The habits of members of the *microgyna* group are somewhat similar to those of the *rufa* group. In these ants the females are exceptionally small; they are usually even smaller than workers.

Family VESPIDAE³⁰

Subfamily VESPINAE

Nests consist of several to many tiers of hexagonal paper cells, the whole generally enclosed in a paper envelope. Larvae are fed chiefly on food of animal origin. The nests are annual; queens hibernates. Species of the subfamily are indigenous to the Northern Hemisphere. A common parasite is *Sphécophaga burra* (Cresson).

Subfamily POLISTINAE

Nests are formed of a single horizontal comb of hexagonal paper cells, attached to a support by a pedicel. The nests are annual and the queen founders are often difficult to distinguish from workers. In cold climates the queens hibernate. Larvae are fed chiefly on food of animal origin. Common parasites or inquiline are *Chalcoela iphitalis* (Walker), *Polistophaga fulva* (Cresson), and *Dicymolomia pegasalis* (Walker).

Subfamily POLYBIINAE

Genus MISCHOCYTARUS Saussure

Revision: Bequaert, 1933. Ent. Amer. (n. s.) 13: 87-150.—Richards, 1945. Roy. Ent. Soc., London, Trans. 95: 295-462.

The nests are similar to those of *Polistes*, but average somewhat smaller. They consist of a single free comb of hexagonal paper cells and are attached by a short pedicel (in North American forms) to a natural or man-made support usually some distance from the ground. Each colony is generally started by a single fertile female or queen.

Revision: Bequaert, 1933. Ent. Amer. (n. s.) 13: 87-112.

The genus is essentially Neotropical but one species extends its range into southern United States. The perennial paper nests are attached to branches of low trees and are begun by small swarms of fertile queens and workers. An average nest is subglobular, is enclosed in a single sheet of papery material, is about 1 foot in diameter, contains about 50,000 cells arranged in layers, has several entrances, and has spiral ramps connecting the tiers of cells. The adults collect and store honey but do not cap the cells.

Subfamily ZETHINAE

Genus ZETHUS Fabricius

Revision: Isely, 1917. Ent. Soc. Amer. Ann. 10: 364-366.

Nests are of various types and some show an approach to social habits. Wood cavities may be utilized as in many strictly solitary wasps, or several females may construct a colony of cells of vegetable fibers or leaves pasted together with a resinous material. In the latter case each wasp feeds its own larvae, using caterpillars. In still other species abandoned cells of *Polistes* and *Mischocyttarus* are used.

Genus STENODYNERUS Saussure

Revision: Bohart, 1943. Brooklyn Ent. Soc. Bul. 38: 6-11 (*Anormis* group).—Bohart, 1944. Pan-Pacific Ent. 20: 69-75 (*Fundatus* group).—Bohart, 1948. Florida Ent. 31: 71-80 (Fla. spp.).—Bohart, 1949. Ent. Soc. Wash. Proc. 51: 237-259 (Ariz. spp.).

Nesting is varied. Species of the *anormis* group nest in twigs; those of the *fundatus* group make original turret-topped ground burrows. Many of the *Parancistrocerus* use hollow twigs but a few occupy old *Sceliphron* nests. Caterpillars are used in provisioning.

Family POMPILIDAE^{31 32}

The taxonomy of the family has been confused, and the literature is consequently hard to use. The classification in many revisionary papers is so different from that presented here that reference to the original descriptions is usually better than consultation of the revisionary literature. The general papers below will often be helpful.

Revisions: Banks, 1911. N. Y. Ent. Soc. Jour. 19: 219-237 (eastern species).—Banks, 1919. Harvard Univ., Mus. Comp. Zool. Bul. 63: 229-248 (western species).—Brimley, 1936. Elisha Mitchell Sci. Soc. Jour. 52: 107-131 (N. C. species).—Dreisbach, 1949. Mich. Acad. Sci., Arts, and Letters Papers 33: 63-71 (American genera).

Members of this family provision their nests with spiders. The nests are usually in the ground, but many of the *Macromerini* construct mud cells in protected places and at least some species of *Dipogon* nest in holes in wood. *Ceropales* is a social parasite on other members of the family, ovipositing on their prey before it is placed in the nest.

³¹By Howard Evans (Pompilinae), P. D. Hurd, Jr. (*Pepsis*), and Henry Townes (other parts of the family).

³²There is division of opinion among the contributors to this catalogue regarding the proper name for the family. Evans and Hurd prefer Pompilidae. Townes prefers Psammocharidae.

³⁶ Pate in 1946 pointed out that the name *Calicurgus* was first published by Brullé in 1833, as a synonym of *Pompilus*. He accepted this mention in synonymy as validating *Calicurgus*, with *Pompilus annulatus*, a species of *Cryptocheilus*, the genotype. To replace the, to him, preoccupied *Calicurgus* of Lepeletier and later authors he proposed the name *Caliadurgus*. Though Pate's action was in harmony with some of the Opinions of the International Commission on Zoological Nomenclature I must state (without at present going into details) that the arguments in favor of acceptance of a mention in synonymy as automatically validating a new name seem weak, and the idea itself absurd and harmful to nomenclatorial stability. So, I believe it correct to continue with the traditional application of the name *Calicurgus*.

Pompilus bombinator Dalla Torre, 1897. Cat. Hym., v. 8, p. 277. N. name.

Tribe **POMPILINI**

Wasps of this tribe are primarily predators on errant or web-spinning

spiders: the majority of species construct a simple gallery in the earth with an enlarged terminal cell, in which a single spider is stored and an egg laid upon it.

Revision: Evans, 1950. Amer. Ent. Soc. Trans. 75: 133-270.

Genus TASTIOTENIA Evans

Family AMPULICIDAE⁴⁰

Kohl, in 1893 (K. K. Naturhist. Hofmus. Ann. 8: 455-516, 3 pls.), presented generic diagnoses, a key to and descriptions of the species of *Ampulex* known to him, and copies of the original descriptions of the other species of Ampulicidae.

So far as is known, the species of this family nest in twigs, under bark, and under leaf litter on the ground, and provision their nests with immature cockroaches.

Genus AMPULEX Jurine

Subgenus AMPULEX Jurine

Ampulex Jurine, 1807. Nouv. Meth. Class. Hym. Dipt., p. 132.

Type: *Spheg compressa* Fabricius. Desig. by Audouin, 1822.

The typical subgenus does not occur in North America.

³⁹ This section is by Karl V. Krombein with the following exceptions: The tribes Larrini and Tachytini by G. E. Bohart; the tribes Philanthini, Bembicini, and Oxybelini by B. D. Burks; the subfamily Sphecinae by W. C. Murray; the tribe Cercerini by H. A. Scullen; and the genus *Astata* by Henry Townes.

The sections by B. D. Burks and Karl V. Krombein were to have been done originally by another contributor. A few months prior to the deadline for submission of the manuscript it was learned that he would be unable to participate. Accordingly little time was available for studying specimens for possible new synonymy and for obtaining further distributional data.

There is considerable variation in the nesting sites and prey preferences of the species. Several species nest in soil and provision with nymphs of Oedipodinae (Orthoptera) or Lygaeidae (Hemiptera), whereas other species nest in twigs or deserted galls and provision with nymphs of Lygaeidae. Probably several subgenera should be recognized, but most of the genotypes are not available.

Subfamily PEMPHREDONINAE⁴⁷Tribe PSENINI⁴⁸

In an excellent revision of the British species Spooner, 1948 (Roy. Ent. Soc., London, Trans. 99: 129-172, 5 figs.) presents biological data which tend to substantiate the generic and subgeneric groupings based

^{47, 48} By Karl V. Krombein, U. S. Bureau of Entomology and Plant Quarantine.

on structural characters. Thus, in Europe, *Psen s. str.* uses larger Auchenorrhyncha (Cercopidae, Membracidae, and Cicadellidae) and nests in ready-made cavities in wood or sandstone; *Mimesa s. str.* excavates burrows in the soil, and stores smaller Auchenorrhyncha (Cicadellidae) which are carried ventrally with the middle legs; *Mimesa (Mimumesa)* also uses smaller Auchenorrhyncha (Delphacidae, Cicadellidae), but carries the prey in the mandibles to nests in cavities in wood and stems; and *Psenulus [recte Diodontus]* preys on Sternorrhyncha (Aphidae, Psyllidae), which are carried ventrally by the middle legs to ready-made cavities in wood or plant stems. The scant biological information, published or unpublished, on Nearctic species indicates a similar correlation: Species of *Psen s. str.* prey on Cercopidae and Membracidae, and nest in wood; *Psen (Pseno)* prey on Membracidae and Cicadellidae (*carolina* was reared from soil in a flowerpot and cocoons of reared specimens of *simplicicornis* bear fragments of wood pulp; *Mimesa s. str.* nest in soil and provision with Cicadellidae; nothing is known as to the biology of our native *Mimesa (Mimumesa)*; *Diodontus* have been reared from lumber and canes of *Rubus*, but the prey is unknown; nothing is known of the biology of *Pluto*, a genus peculiar to the New World, but presumably the species nest in soil.

Subfamily SPHECINAE⁵⁰

Tribe SPHECINI

There is only one genus, *Spheg*, in this tribe. These wasps store their nests with Acrididae, Tettigoniidae, and Gryllidae. The various subgenera of *Spheg* apparently select certain groups of Orthoptera to the exclusion of others. Odd records in the literature indicate either that these selections are not absolutely fixed or that we are in need of more observations and positive identifications.

Genus SPHEX Linnaeus⁵¹

Revisions: Kohl, 1890. K. K. Naturhist. Hofmus. Ann. 5: 77-194, 317-462.—
Fernald, 1906. U. S. Natl. Mus. Proc. 31: 291-423.

The treatment of *Spheg* has been conservative. It is recognized that some changes will have to be made in the future, but it is believed best to wait until a comprehensive revisional work has been made in order to insure stability.

⁵⁰ By William Donald Murray, Visalia, Calif.

⁵¹ The editors are not in agreement with the generic nomenclature employed by Dr. Murray for *Spheg* and *Ammophila*. It is our conviction that Opinion 180 (Internatl. Comn. Zool. Nomencl., 1946) constitutes a reversal of Opinion 32 which established *sabulosa* L. as the type of *Spheg*. The reversal of a previous opinion requires an affirmative vote by three-fourths of all the Commissioners (By-Laws, Internatl. Comn. Zool. Nomencl.). Since only 12 Commissioners out of 17 voted on Opinion 180, the opinion has no legality and we do not feel bound by it. Those who agree with this interpretation of the facts, and who wish to use the names as established by Opinion 32 and confirmed by usage in such major revisionary papers as Fernald's and Murray's on the North American fauna and Arnold's on the African fauna, will have to make the following changes in this catalog:

Tribe Sphecini, p. 971, becomes Chlorionini

Genus *Spheg*, p. 971, becomes Genus *Chlorion*

Subgenus *Ammobia* will replace Subgenus *Spheg*, p. 971.

Tribe Ammophilini, p. 974, becomes Sphecini

Genus *Ammophila*, p. 974, becomes *Spheg*

Genus BEMBIX Fabricius

Bembix Fabricius, 1775. Systema Ent., Char. Gen., p. [11]; text [*Bembyx* (!)], p. 361.

Type: *Vespa signata* Linnaeus. Monob.

Bembex Fabricius, 1777. Gen. Ins., p. 122. Emend.

Monedula Latreille, 1802. Hist. Nat. Crust. Ins., v. 3, p. 343. Preocc.

Type: *Vespa signata* Linnaeus. Desig. by Latreille, 1810.

Stictia Illiger, 1807. In Rossi, Fauna Etrusca, Ed. 2, v. 2, p. 131. N. name for *Monedula* Latreille.

Wasps of this genus stock their nests with flies and practice progressive provisioning.

carolina (Fabricius), n. comb. N. J. and Pa. south to Fla., west to Ill., Kans., and N. Mex. Prey: Principally horse flies, *Chrysops* spp. and *Tabanus* spp.; occasionally also *Odontomyia cincta* Oliv., *Psorophora ciliata* (F.), *Orthellia cornicina* (F.), and *Callitroga* sp.

Bembex carolina Fabricius, 1793. Ent. System., v. 2, p. 249.

Biology: Hine, 1906. La. State Crop Pest Comm. Cir. 6: 20-27.—Hine, 1907. La. Agr. Expt. Sta. Bul. 93: 13-15.

signata (Linnaeus). Fla., Calif., So. and Cent. Amer., West Indies. Prey: *Chrysops* sp. and numerous other fairly large flies.

Vespa signata Linnaeus, 1758. Syst. Nat., Ed. 10, v. 1, p. 574.

Genus EPIBEMBEX Minkiewicz

Bembex and *Bembix* of authors, not of the genotype.

Epibembex Minkiewicz, 1934 (1933). Polski Pismo Ent. 12: 254.

Type: *Apis rostrata* Linnaeus. Desig. by Pate, 1937.

Apobembex Minkiewicz, 1934 (1933). Polski Pismo Ent. 12: 254.

Type: *Bembex oculata* Latreille. Desig. by Pate, 1937.

Biology: Nielsen, 1933. Ent. Meddel. 18 (3): 296-299.—Nielsen, 1945. Zool. Mus. Hauniensis, Copenhagen, Spolia 7: 1-174.

Taxonomy: Lohrmann, 1948 (1944). München. Ent. Gesell. Mitt. 34: 420-432.

Most of the wasps in this genus provision their nests with flies, but a few prey on immature Hemiptera.

Genus ENCOPOGNATHUS Ashmead

The name *Encopognathus* was first employed by Kohl, 1896 (K. K. Naturhist. Hofmus. Ann. 11: 485, 486). However, it may not be validated from that date, for Kohl proposed it as a name for a species group ("Arten-gruppe") of the subgenus *Lindenius*. The earliest use of the name in a generic or subgeneric sense was by Ashmead, 1899, who characterized it as a genus.

The species nest in soil, and African forms are known to provision their nests with ants. The prey of the American species has not been discovered.

Subgenus PARANTHYREUS Ashmead

Paranthyreus Ashmead, 1899. Canad. Ent. 31: 213.

Type: *Crabro hilaris* Smith. Orig. desig.

The name *Paranthyreus* was first employed by Kohl, 1896 (K. K. Naturhist. Hofmus. Ann. 11: 490). However, it may not be validated from that date, for Kohl proposed it as a name for a subgenus ("Unter-

gruppe") of the species group ("Artengruppe") *Thyreopus* of the subgenus *Crabro*. The earliest use of the name in a generic or subgeneric sense was by Ashmead, 1899, who characterized it as a genus.

Family DRYINIDAE⁶³

Comparatively few North American specimens of this family that are collected can be identified at present since the group is virtually unstudied. Most Nearctic species appear to be still undescribed; and many of the species listed here are probably not referred to the genera in which they really belong. A large proportion of them are known only from the unique types. Moreover, the sexes are so strongly dimorphic, except in the subfamily Aphelopinae, that they can be positively associated only by rearing. Apparently most species of the family are parasites of Homoptera, especially Cicadellidae and Fulgoroidea; but definite rearing records are few.

Genus BOMBUS Latreille

The genus *Bombus* comprises medium to large-sized, nest-building, social species, each of which has a worker caste and a primary reproductive caste of males and females. The females, or queens, and the workers have pollen-collecting baskets on the hindlegs. These bees live in colonies in or on the ground, often in the deserted nests of rodents.

Unplaced Species in Genus *Bombus*

Apis pennsylvanica Degeer, 1773. Mém. Serv. Hist. des Ins., v. 3, p. 575. Possibly this is the species now being called *Bombus fervidus* (Fabricius); the name *pennsylvanicus* commonly has been used for the species here called *Bombus americanorum* (Fabricius).

Bombus praticola Kirby, 1837. Fauna Bor.-Amer., v. 4, p. 274. This may be the species now being called *Bombus pleuralis* Nylander.

Bombus bruneri Swenk, 1938. Pan-Pacific Ent. 14: 29. ♀. Said to be allied to *Bombus dahlbomii* Guérin, a South American species; *bruneri* was described from Texas.

Apis marylandica Fabricius, 1798. Sup. Ent. System., p. 273. This evidently is a *Bombus*, but is not recognizable specifically; it may not be a nearctic species.

Genus *PSITHYRUS* Lepeletier

The genus *Psithyrus* contains a few species of obligate social parasites on the members of the genus *Bombus*. They closely resemble the species of *Bombus*, but lack the worker caste, and the queens lack pollen-collecting baskets on the hind legs.

Biology: Plath, 1922. Biol. Bul. 43: 23-44.

Subgenus *PSITHYRUS* Lepeletier

Psithyrus Lepeletier, 1832. Soc. Ent. France Ann. 1: 372.

Type: *Apis rupestris* Fabricius. Desig. by Curtis, 1833.

Apathus Newman, 1835. Ent. Mag. 2: 404, footnote.

Type: *Apis rupestris* Fabricius. Autobasic with *Psithyrus*; name proposed to replace *Psithyrus*, thought to be preoccupied by *Psithyros* Hübner, 1819.

The typical subgenus does not occur in North America.

Subgenus *ASHTONIPSITHYRUS* Frison

Psithyrus subg. *Ashtonipsithyrus* Frison, 1927. Amer. Ent. Soc. Trans. 53: 69.

Psithyrus wheeleri Bequaert and Plath, 1925. Mus. Compar. Zool. Bul. 67: 265. ♀ ♂.

Unplaced Species in Genus *Psithyrus*

- Apis alata* Fabricius, 1798. Sup. Ent. System., p. 274.
Bombus elatus Fabricius, 1804. Systema Piezatorum, p. 352. These two names refer to the same Fabrician species, *alata* evidently having been a misprint for *elata* in the 1798 edition. *Psithyrus laboriosus* (Fabricius), 1804, possibly is the same.

Tribe APINI⁹⁴

Genus *APIS* Linnaeus

- Apis* Linnaeus, 1758. Syst. Nat., Ed. 10, p. 343.
 Type: (*Apis mellifica* Linnaeus)=*Apis mellifera* Linnaeus. Desig. by Latreille, 1810.
- Apairus* Rafinesque, 1815. Analyse Nature ou Tabl. Univers, Palmero, p. 123. Proposed unnecessarily to replace *Apis*.

 Type: *Apis florea* Fabricius. Monob. and orig. desig.
- mellifera** Linnaeus. Worldwide. Introduced in Western Hemisphere. Represented in the Old World by numerous subspecies, several of which have been introduced into North America with the result that much interbreeding has occurred among them. The escaped bees of the woodlands are largely *A. mellifera mellifera* (German bee) while the beekeepers' bees are largely *A. mellifera ligustica* (Italian bee). *A. mellifera remipes* (Caucasian bee) is also utilized by some beekeepers. For convenience these forms are listed below in the synonymy.
- Apis mellifera* Linnaeus, 1758. Syst. Nat., Ed. 10, p. 576.
Apis mellifica Linnaeus, 1761, Fauna Suecica, Ed. 2, p. 421. Proposed unnecessarily to replace *mellifera*.
